Subject: Biology Audit

Answer: Based on the students data I can conclude that plastic type B has the largest amount stretched. Two ways that the student could have improved the experimental decision is by allowing the weights to hang longer to see if the plastic would stretch more. Another way he could have improved his experiment is by doing a third trials to really be sure that his results are correct.

Name: Student_558

Subject: Biology Audit

Answer: A. Sample B plastic has the most stretchability. B. One way it to add the original length of the plastic to the chart so you can find the difference of the original and after it stretched. Another way is to show the weight of the weights being put on.

Name: Student_559

Subject: Biology Audit

Answer: The stretchiest plastic was plastic B in both trials. And the least stretchiest plastic was plastic A in both trials. ^p The student could have improved the experiment by adding a control and using the same length of each plastic.

Name: Student_560

Subject: Biology Audit

Answer: a. Conclusion: type a plastic stretched the most. ^p b. The student have used the same length of plastic for every type and should have did more than one trial.

Name: Student_561

Subject: Biology Audit

Answer: a) Plastic type A and B stretched after being pulled apart for five minutes. Plastic type C and D either shrank in length or stayed the same.^p b) The student should of added a control by hanging the plastics with no weight. Also the student should specify how much weight is on the clamp.

Name: Student_562

Subject: Biology Audit

Answer: A.) Based on the data of the table, I conclude that plastic B was the most stretchable. In both trials it proved to be always above 20mm. ^P B.) The student could've used different clamps in his trials, this would've expanded the student possibilities with the plastics. To help with the validity, the student could explain what he did different. For trial T2, for the measures are not the same as T1 except for plastic type D, in both trials the measures were the same.

Name: Student_563

Subject: Biology Audit

Answer: The conclusion that I have drawn is that plastic B was the strongest. Plastic B was the strongest because in trial one it stretched the most to 22mm. Ther trial two B stretched to 23mm. To improve the experiment design the student could state a length they want the sample plastic to be. In the procedure the student should have stated labels that she/he was measuring in.

Name: Student_564

Subject: Biology Audit

Answer: A conclusion that can be drawn from the student's experiment is that plastic B is able to stretch the farthest (T1:22mm, T2:23mm) and plastic A stretched the least (T1:10mm, T2:12mm). The validity of this experiment could have been improved greatly by doing these two things; 1) Making sure that the starting length of the plastics were all the same and 2) determining how much of the plastic will be stretched to the table at the beginning. By doing these two things, you're ensuring controlled variables therefore validating your experiment

Name: Student_565

Subject: Biology Audit

Answer: B. Two ways the students could improve the experiment is to doing it again and again until you get the same results. Another way could to leave the plastics hanging for longer.

Name: Student_566

Subject: Biology Audit

Answer: I conclude that plastic type B is the most stretchable because according to the data plastic B in trial 1 stretched 22mm and trial 2 23mm unlike plastic type A which in T1 stretched 0mm and in trial 2 2mm. One way the students could have improved their experiment would be of saying exactly how much weights to add and keep it the same for all the plastics. Another way they could have improved this experiment would be by having the same length of plastic for all the plastics, also they could have done more trials to improve their experiment.
